

## Documentation: MIP Function – Feature Ranking for Structured Targets

The feature ranking algorithm for structured target variables.

### *Metadata*

## **Description**

Methods for feature ranking are used in many domains with many descriptive variables, i.e., high-dimensional problems. The obtained rankings provide an additional insight about the importance of the variables for the target and/or reduce the dimensionality of the problem. Many real-life problems have structured targets that need to be predicted. However, the task of feature ranking in the context of predicting structured target variables is more complex than the same task for simple classification or regression. Typical approaches for this task decompose the output to primitive components, perform feature ranking on these smaller problems, and then aggregate the resulting rankings into a single ranking. They are computationally intractable for large output spaces (e.g., genetic or imaging data) and ignore the dependencies between components of the output. We have developed efficient feature ranking methods in the context of predicting structured targets. The developed methods are based on the ensemble learning paradigm.

This MIP function implements two algorithms for feature ranking for structured targets: (1) RF-RANK exploits the random forests mechanism and (2) GENIE3 exploits the variance reduction at each tree node from the ensemble. For the latter method, the ensemble could be random forest or an ensemble of extra trees. The both methods use predictive clustering trees as base predictive models.

The development of the algorithm and its implementation was partly paid by HBP.

## **Usage**

Input: A set of examples with known values for descriptive and target variables.

Parameters: Descriptive variables, target variables, number of trees in the ensemble, size of the feature subsets considered at each node.

Output: A list of the descriptive variables and their importance to the structured target.

## **Example**

We can illustrate the use of the algorithm on the ADNI data.

Task:

Given a data set consisting of examples (i.e., patients) described in terms of several descriptive variables and labelled with several target variables we want to learn a feature ranking that will order the descriptive variables based on their importance for the target variables.

## Input data:

Given a subset of ADNI data with 916 patients described with 34 different variables, collected at baseline evaluation, we split the variables in two groups. In the first group we have descriptive variables: APOE4, Ventricles, Hippocampus, WholeBrain, Entorhinal, Fusiform, MidTemp, ICw, FDG, Aw45, CDRSB, ADAS13, MMSE, RAwLT\_immediate, RAwLT\_learning, RAwLT\_forgetting, RAwLT\_perc\_forgetting, FAQ, MOCA. In the second group we have the target variables: EcogPtMem, EcogPtLang, EcogPtwisspat, EcogPtPlan, EcogPtOrgan, EcogPtDiwatt, EcogPtTotal, EcogSPMem, EcogSPLang, EcogSPwisspat, EcogSPPlan, EcogSPOrgan, EcogSPDiwatt, EcogSPTotal. We decided to learn a feature ranking with RF-GENIE parametrized as follows: random forest of 100 trees using SQRT of the descriptive features at each node of the trees.
